

Principle of Ceramic Flanged Optical Splitter

Overview

By dividing a single optical signal from a central Optical Line Terminal (OLT) into multiple outputs for Optical Network Terminals (ONTs) at users' homes, splitters eliminate the need for dedicated fibers to each residence—slashing infrastructure costs while scaling network reach. Optical splitters, also known as fiber optic splitters, are integral components in fiber optic networks, enabling one fiber input to be divided into multiple outputs. This capability is crucial in telecommunications, especially in Passive Optical Networks (PONs), where fiber-optic networks must. Bandwidth is shared amongst customers in a PON, and the bandwidth received by a customer is not related to the power received at the optical network terminal (ONT) as long as the power is high enough so the ONT can operate. Conversely, it can also combine multiple signals into one. It is widely used in passive optical networks (such as EPON, GPON, BPON, FTTX, FTTH, etc).
